1 Introduction

1.1 Motivation

The goal of JaTesté is to design a language that promotes good coding practices - mainly as it relates to testing. JaTesté will allow the programmer to easily define test cases, for any function, directly into his or her source code. This will ensure that no code goes untested and will increase the overall quality of programmer code written in our language. By directly embedding test cases into source code, we remove the hassle associated with manually creating test files.

1.2 Language Description

JaTesté is an imperative, C-like language, with a few object oriented features added, that makes it easy to add test cases to ones code. The syntax is very similar to C, but with the added capability of associating functions with “structs”, similarly to how methods are implemented in objects in Java. Test cases are easily appended to user-defined functions, by appending the keyword “with test” onto the end of a function. The compiler subsequently outputs two separate files: 1) a regular executable 2) an executable test file that runs all user defined tests.

1.3 Related Work

The JaTesté syntax is very much inspired by C and Java, two of the most popular programming languages in use today. Nonetheless, JaTesté’s syntax is relatively simple, as so anyone with basic, imperative programming language experience should be able to pick it up quickly.

2 Short Tutorial

2.1 Environment

The compiler was developed and tested on an Ubuntu 15.10 virtual machine. We ran the Linux image through VirtualBox, but any standard hypervisor should suffice.

The compiler translates JaTest  source code into LLVM, a portable assembly-like language. You need to download LLVM from <http://llvm.org/releases/download.html> in order to run LLVM code.

The compiler is written completely in OCaml. The OCaml compiler can be downloaded from <http://caml.inria.fr/download.en.html>

2.2 Using the JaTest  Compiler

From any given JaTest  source file, the compiler generates (1) an executable file, and if the “-t” command line argument is supplied, (2) an executable test file with all the relevant user-defined test cases. This relieves the programmer from having to manually create test files from scratch. All code is compiled into LLVM, a portable assembly-like language. To run the compiled LLVM code, we use ‘lli’, an LLVM interpreter.

For (1) the regular executable, the compiler completely disregards the tests and thus produces an executable as if the test cases had never been written. This enables the programmer to produce a regular executable without the overhead of the test cases when he or she desires. Thus, while a JaTest  program can be embedded with an unlimited number of test cases, the programmer can always generate a standard runnable program without the test case code.

For the test file, the compiler turns each test case into its own function, and subsequently runs each of these functions from a brand new, compiler generated “main” function. “main” simply runs through each of these compiler-generated functions, each of which runs the user-defined tests. Furthermore, the compiler adds “print” calls to each test letting the user know whether a given test passed or failed.

When inside the src folder, type “make all” to generate the Jatest  executable. To run type ./jatest .native [optional -options] <source_file.jt>

The possible arguments are:

- No arguments If run without arguments, the compiler ignores the test cases and creates a regular executable, source_file.ll, as if the test cases were never there to begin with.
- “-t” Compile with test This results in the compiler creating two LLVM files: 1) a regular executable named “source_file.ll” as above, and 2) a test file named “source_file-test.ll”. Both of these are LLVM executables.
- “-l” Scan only This results in the compiler simply scanning the source code. This is mainly used for debugging purposes.
- “-p” Parse only This results in the compiler simply parsing the source code. Also mainly used for debugging purposes.
- “-se” SAST This results in the compiler running the semantic checker on the source code and then stopping. Also mainly used for debugging purposes.
- “-ast” AST This also results in the compiler running the semantic checker on the source code and then stopping. Also mainly used for debugging purposes.

A maximum of one command line argument at a time can be supplied when running the compiler.

2.3 JaTest  Program Structure

Any given JaTest  program can be broken down into four segments:

1. List of includes. JaTest  programs can include other JaTest  source code files. This list should go at the top of the source code file.

2. global variable declarations. Global variable declarations are exactly like in C and immediately follow included headers.
3. function definitions. Function definitions are similar to C, except the keyword “func” is needed before the return type. Furthermore, all variable declarations must be done at the beginning of each function. A “main” function is required for all JaTesté programs; this is where execution starts when a program is run. Included JaTesté headers shouldn’t have a “main” function, however.
4. struct definitions. Structs are also similar to C, except the programmer can define methods within the struct. All struct fields must be declared before the struct’s methods. The syntax for struct methods is exactly like any regular function, except the keyword “method” is used instead of “func”.

Each of these segments must be used in the order given above.

2.4 Programming Language Paradigm

2.4.1 Imperative Paradigm

JaTesté is a pretty standard imperative programming language that has light object-oriented features. Since JaTesté is not functional, functions can have side-effects. Anyone familiar with C, C++, or Java should have any especially easy time understanding JaTesté.

2.4.2 Pass-by-value

JaTesté is a pass-by-value programming language. Nonetheless, there is strong support for pointers which gives the programmer the ability to pass by reference. & is used to get the address of a variable. *<type> is used to declare a variable as a pointer type. * can subsequently be used to dereference a pointer.

2.4.3 Typing

All variables must be declared along with their respective type before they are used. JaTesté has relatively strict typing checking - values of different types cannot be cast to each other. Note, void pointers are not allowed; that is, pointers must define what data type they are pointing to.

2.4.4 Memory Layout

Global variables are stored in the data section, local variables are allocated on the stack, arrays and structs can be allocated on the stack with the “new” keyword, and code is stored in the text segment of the program. When external JaTesté headers are included, the respective code is simply appended to the source code file. Thus, the memory layout of a given JaTesté program is pretty standard.

2.5 Basics

2.5.1 Primitives

JaTesté supports the following primitives:

- int
- double
- char
- boolean
- string

2.5.2 Arrays

In JaTesté, an array of type “t” and size “n” is an allocated block of memory that holds n contiguous values all of type t. This exactly how arrays are implemented in C, C++, and Java. They can be allocated on the stack or heap.

2.5.3 Structs

Structs in JaTesté are just like in C, but with the added capability of giving them methods. This makes it easier to associate functions with the data they are meant to manipulate. Structs can be allocated on the stack or heap.

2.5.4 Operators

JaTesté supports the following operators:

- Arithmetic: +, -, *, ^, %, \
- Logical: &&, ||
- Relational: ==, <, <=, !=, >, >=

2.5.5 Control Flow

JaTesté supports standard control flow constructs, such as for and while loops, and if-else statements. “return” is used to return control to the caller, as in almost any other programming language.

2.5.6 Test Cases

Test cases are used to test user-defined functions, and are at the heart of the JaTesté programming language. The best way to illustrate how to take advantage of JaTesté’s built in testing functionality is through an example:

```
1 func int add(int x, int y)
2 {
3     return x + y;
4 } with test {
5     assert(add(a,0) == 10);
6     assert(add(b,b) == 10);
7     assert(add(a,b) == 15);
8 } using {
9     int a;
10    int b;
11    a = 10;
12    b = 5;
13 }
```

Here we’ve defined a function, “add”, and appended a few test cases using the built-in “with test” and “using” keywords. It is within “with test { ... }” where the programmer actually defines his or her tests. In this example, the programmer is verifying that the add() function returns the correct value for three specific inputs. Notice how each test uses variables “a” and/or “b”; these variables are defined inside “using { ... }”. Thus, “using { ... }” is used to set up the environment for the test cases. This makes it easier for the programmer to write meaningful “assert” statements inside the “with test { ... }” testing block.

2.6 Sample Programs

Here are a few example programs.

1. Here’s the first example of a JaTesté program. As illustrated, the syntax is very similar to C.

```

1 #include_jtlib <math.jt>
2 int my_global;
3
4 func int main()
5 {
6     int i;
7     i = add(2,3);
8     if (i == 5) {
9         print("passed");
10    }
11    return 0;
12 }
13
14
15 func int add(int x, int y)
16 {
17     return x + y;
18 } with test {
19     assert(add(a,0) == 10);
20 } using {
21     int a;
22     int b;
23     a = 10;
24     b = 5;
25 }
26
27 struct house {
28     int price;
29     int zipcode;
30 };

```

Note the structure of the program. More specifically, include files are specified at the top, global variables are declared next, functions definitions are coded in the middle, and structs are defined at the end of the source file.

As can be seen the “add” function has a snippet of code directly following it. This is an example of a program that takes advantage of JaTesté’s built-in testing framework. The code within the “with test” block defines the test cases for the add function, via an assert statement. In this case, the programmer has only specified one test. Furthermore, note the code following the test case that starts with “using { ... }”. This block is used to set up the environment for the test cases. In this example, the single test case “assert(a == 10);” references the variable “a”; it is within the scope of the “using ” block that “a” is defined.

2. Here’s another JaTesté program:

```

1 func int main()
2 {
3     int a;
4     int b;
5     int c;
6
7     a = 10;
8     b = 5;
9     c = 0;
10
11    a = b - c;
12    if (a == 5) {

```

```

13         print("passed");
14     }
15     return 0;
16 }
17
18
19 func int sub(int x, int y)
20 {
21     return x - y;
22 } with test {
23     assert(sub(10,5) == b - 5);
24     assert(sub(b,d) == 1);
25     assert(sub(c,d) == 4);
26 } using {
27     int a;
28     int b;
29     int c;
30     int d;
31     a = 5;
32     b = 10;
33     c = 13;
34     d = 9;
35 }

```

This example is similar to the previous one; however, note that there are now multiple “asserts”. The programmer may define as many test cases as he or she wants. When compiled with the “-t” command line argument, the compiler creates a file “test-testcase2-test.ll” (the name of the source program being “test-testcase2.jt” in this case) in addition to a regular executable (which would be named testcase2.ll in this case). When “lli test-testcase2-test.ll” is run, the output is:

Tests:

subtest tests:

sub(10,5) == b - 5 passed

sub(b,d) == 1 passed

sub(c,d) == 4 passed

As illustrated, the test program will let you know which tests pass and which fail.

3. Here we introduce structs. The syntax is very similar to C:

```

1  int global_var;
2
3  func int main()
4  {
5      int tmp;
6      struct rectangle *rec_pt;
7      rec_pt = new struct rectangle;
8      update_rec(rec_pt, 6);
9      tmp = rec_pt->width;
10
11     print(tmp);
12
13     return 0;
14 }
15
16 func void update_rec(struct rectangle *p, int x)
17 {
18     p->width = x;
19 } with test {

```

```

20     assert(t->width == 10);
21 } using {
22     struct rectangle *t;
23     t = new struct rectangle;
24     update_rec(t, 10);
25 }
26
27 struct rectangle {
28     int width;
29     int height;
30 };

```

Again, note the syntax of the whole program here. More precisely, global variables are declared at the top, functions are defined in the middle, and structs are defined at the bottom. Note, this file does not use any header files; these would go above the global variable declaration. This is the required order for *all* JaTesté programs.

4. As previously explained, JaTesté is a pass-by-value programming language. For those familiar with C, this paradigm should be very familiar. For those not, this simply means every variable is passed around by value, not address. Pointers can be used to mimic pass-by-reference as the following example shows:

```

1 func int main()
2 {
3     int a;
4     int b;
5     int *c;
6
7
8     a = 10;
9     b = 500;
10
11     c = &b;
12
13     if (*c == 500) {
14         print("passed");
15     } else {
16         print("failed");
17     }
18
19     return 0;
20 }

```

& is used to return the address of a variable, as is done on line 11 of this program. * is used to declare a variable as a pointer, as is done with the variable “c” above on line 5. Thus, line 11 sets the variable “c” to the address of “b”. Since “b” contains value 500, and “c” contains the address of “b”, we can say that “c” points to “b’s” value of 500. * can subsequently be used to dereference pointers, as is done on line 13 inside “if (*c == 500)”. Here, we use * to access the value pointed to by “c”, which is “b’s” value of 500 and so the expression inside the if-statement will evaluate to true.

5. All variables are allocated on the stack, unless the “new” keyword is used in conjunction with structs and/or arrays, as the following example illustrates.

```

1 func int main()
2 {
3
4     struct house *my_house;
5     int price;
6     int vol;

```

```

7
8     my_house = new struct house;
9
10    my_house->set_price(100);
11    my_house->set_height(88);
12    my_house->set_width(60);
13    my_house->set_length(348);
14
15    price = my_house->get_price();
16    vol = my_house->get_volumne();
17
18    print(price);
19    print(vol);
20    return 0;
21 }
22
23 struct house {
24     int price;
25     int height;
26     int width;
27     int length;
28
29     method void set_price(int x)
30     {
31         price = x;
32     }
33
34     method void set_height(int x)
35     {
36         height = x;
37     }
38
39     method void set_width(int x)
40     {
41         width = x;
42     }
43
44 };

```

The line `my_house = new struct house;` is used to allocate memory on the heap for a struct object. Note “`->`” is used to access the given structs methods. This syntax is required because `my_house` is a pointer to a struct. If `my_house` was a regular house struct variable, and not a pointer, a dot would suffice (e.g. `my_house.set_price(100);`) This example also illustrates the use of methods within structs. Unlike C, you can directly embed methods in structs. The functionality is very similar to how methods work in object-oriented languages.

3 Language Reference Manual

3.1 Lexical Conventions

This section will describe how input code will be processed and how tokens will be generated.

3.1.1 Identifiers

Identifiers are used to name variables as in most programming language. An identifier can include all letters, digits, and the underscore character. An identifier must start with either a letter or an underscore - it cannot start with a digit. Capital letters will be treated differently from lower case letters. The set of keyword, listed below, cannot be used as identifiers.

Here's the regular expression for an identifier:

```
[ 'a' - 'z' 'A' - 'Z' ] [ 'a' - 'z' 'A' - 'Z' '0' - '9' '_' ] * as lxm { ID(lxm) }
```

3.1.2 Keywords

Keywords are a set of words that serve a specific purpose in our language and may not be used by the programmer for any other reason. The list of keywords the language recognizes and reserves is as follows:

if, else, return, while, for, assert, void, struct, method, double, int, char, string, bool, true, false, func, new, free, NULL Each keyword's meaning will be explained at some point later in this chapter.

3.1.3 Constants

Our language includes integer, character, real number, and string constants. They're defined in the following sections.

3.1.4 Integer Constants

Integer constants are a sequence of digits. An integer is taken to be decimal. The regular expression for an integer is as follows:

```
digit = [ '0' - '9' ]  
int = digit +
```

3.1.5 Double Constants

Real number constants represent a floating point number. They are composed of a sequence of digits, representing the whole number portion, followed by a decimal and another sequence of digits, representing the fractional part. Here are some examples.

```
let double = (digit+) [ '.' ] digit +
```

3.1.6 Character Constants

Character constants hold a single character and are enclosed in single quotes. They are stored in a variable of type "char". The regular expression for a character is as follows:

```
let my_char = ''' [ 'a' - 'z' 'A' - 'Z' ] '''
```

3.1.7 String Constants

Strings are a sequence of characters enclosed by double quotes. A String is treated like a character array. The regular expression for a string is as follows:

```
my_string = '"' ([ 'a' - 'z' ] | [ ' ' ] | [ 'A' - 'Z' ] | [ '_' ] | [ '!' | ',' ]+ )+ '"'
```

Strings are immutable; once they have been defined, they cannot change.

3.1.8 Operators

Operators are special tokens such as multiply, equals, etc. that are applied to one or two operands. Their use will be explained further in section 3.2.

3.1.9 White Space

White space is considered to be a space, tab, or newline. It is used for token delimitation, but has no meaning otherwise. That is, when compiled, white space is thrown away.

```
WHITESPACE = "[ ' ' '\t' '\r' '\n' ]"
```

3.1.10 Comments

A comment is a sequence of characters beginning with a forward slash followed by an asterisk. It continues until it is ended with an asterisk followed by a forward slash. Comments are treated as white space.

```
COMMENT = "/\* [^ \*/]* \*/ "
```

3.1.11 Separators

Separators are used to separate tokens. Separators are single character tokens, except for white space which is a separator, but not a token.

```
'('      { LPAREN }  
)'      { RPAREN }  
'{'      { LBRACE }  
'}'      { RBRACE }  
';'      { SEMI  }  
' ,'     { COMMA }
```

3.2 Data Types

The data types in JaTeste can be classified into three categories: primitive types, structures, and arrays.

3.2.1 Primitives

The primitives our language recognizes are int, double, bool, char, and string.

3.2.2 Integer Types

The integer data type is a 32 bit value that can hold whole numbers ranging from $-2,147,483,648$ to $2,147,483,647$. Keyword `int` is required to declare a variable with this type. A variable must be declared before it can be assigned a value; this cannot be done in one step.

```

1 int a;
2 a = 10;
3 a = 21 * 2;

```

The grammar that recognizes an integer declaration is:

```
typ ID
```

The grammar that recognizes an integer initialization is:

```
ID ASSIGN expr
```

3.2.3 Boolean Types

The “bool” type is your standard Boolean data type that can take on one of two values: 1) true 2) false. Booleans get compiled into 1 bit integers.

```

1 bool my_bool;
2 my_bool = true;

```

3.2.4 Double Types

The double data type is a 64 bit value. Keyword `double` is required to declare a variable with this type. A variable must be declared before it can be assigned a value, this cannot be done in one step just like with ints.

```

1 double a;
2 a = 9.9;
3 a = 17 / 3;

```

The grammar that recognizes a double declaration is:

```
typ ID
```

The grammar that recognizes a double initialization is:

```
ID ASSIGN expr
```

3.2.5 Character Type

The character type is an 8 bit value that is used to hold a single character. Like most programming languages, characters in Jateste get compiled into a 1 byte integer. The keyword `char` is used to declare a variable with this type. A variable must be declared before it can be assigned a value.

```

1 char a;
2 a = 'h';

```

The grammar that recognizes a char declaration is:

```
typ ID SEMI
```

The grammar that recognizes a char initialization is:

```
typ ID ASSIGN expr SEMI
```

3.2.6 String Type

The string type is variable length and used to hold a string of chars. The keyword **string** is used to declare a variable with this type. A variable must be declared before it can be assigned a value, as with all variables.

```
1 string a;  
2 a = "hello";
```

The grammar that recognizes a char declaration is:

```
typ ID SEMI
```

The grammar that recognizes a char initialization is:

```
typ ID ASSIGN expr SEMI
```

3.2.7 Structures

The structure data type is a user-defined collection of primitive types, other structure data types and, optionally, methods. The keyword “struct” followed by the name of the struct is used to define structures. Curly braces are then used to define what the structure is actually made of. As an example, consider the following:

3.2.8 Defining Structures

```
1 struct square {  
2     int height;  
3     int width;  
4  
5     method int get_area()  
6     {  
7         int temp_area;  
8         temp_area = height * width;  
9         return temp_area;  
10    }  
11  
12    method void set_height(int h) {  
13        height = h;  
14    }  
15  
16    method void set_width(int w) {  
17        width = w;  
18    }  
19 };  
20  
21  
22 struct manager = {  
23     struct person name;  
24     int salary;  
25 };
```

Here we have defined two structs, the first being of type **struct square** and the second of type **struct manager**. Note square struct has methods associated with it, unlike the manager struct which is just like a regular C struct. The grammar that recognizes defining a structure is as follows:

```
STRUCT ID LBRACE vdecl_list struc_func_decls RBRACE SEMI
```

3.2.9 Initializing Structures

To create a structure on the heap, the “new” keyword is used:

```
1 struct manager *yahoo_manager;  
2 struct person sam;  
3  
4 yahoo_manager = new struct manager;  
5 sam = new struct person;
```

NEW STRUCT ID

Here, we create two variables yahoo_manager and sam on the heap. The first is of type “struct manager”, and the second is of type “struct person”. When using the “new” keyword, the memory is allocated on the heap for the given struct. “free(p)” is used to de-allocate heap memory pointed to by “p”. Structs can also be allocated on the stack as follows:

```
1 struct manager yahoo_manager;  
2 struct person sam;
```

3.2.10 Accessing Structure Members

To access structs allocated on the heap, and modify its variables, a right arrow C is used followed by the variable name:

```
1 yahoo_manager->name = sam;  
2 yahoo_manager->age = 45;  
3 yahoo_manager->salary = 65000;
```

If the struct is allocated on the stack, just use a dot as follows:

```
1 yahoo_manager.name = sam;  
2 yahoo_manager.age = 45;  
3 yahoo_manager.salary = 65000;
```

expr DOT expr

3.2.11 Using Structure Methods

Methods are accessed in the same way as fields: if the struct is allocated on the stack, use a dot, otherwise use a right arrow.

```
1 struct square p;  
2 int area;  
3 p.height = 7;  
4 p.width = 9;  
5 area = p.get_area();  
6 p.set_height(55);  
7 p.set_width(3);  
8 area = p.get_area();
```

```
1 struct square *p;  
2 int area;  
3 p = new struct square;  
4 p->height = 7;
```

```

5      p->width = 9;
6      area = p->get_area();
7      p->set_height(55);
8      p->set_width(3);
9      area = p->get_area();

```

3.2.12 Arrays

An array is a data structure that allows for the storage of one or more elements of the same data type contiguously in memory. Each element is stored at an index, and array indexes begin at 0. This section will describe how to use Arrays.

3.2.13 Defining Arrays

An array is declared by specifying its data type, name, and size. The size must be positive. Here is an example of defining an integer array on the heap with size 5:

```

1  arr = new int[5];

```

```
ID ASSIGN NEW prim_typ LBRACKET INT_LITERAL RBRACKET
```

You can also create arrays on the stack as follows:

```

1  int arr[10];

```

It is not required to initialize all of the elements. Elements that are not initialized will have a default value of zero.

3.2.14 Accessing Array Elements

To access an element in an array, use the array name followed by the element index surrounded by square brackets. Here is an example that assigns the value 1 to the first element (at index 0) in the array:

```

1  arr[0] = 1;

```

Accessing arrays is simply an expression:

```
expr LBRACKET INT_LITERAL RBRACKET
```

The syntax is the same for arrays allocated on the heap or stack. Also, JaTeste does not test for index out of bounds, so the following code would compile although it is incorrect; thus it is up to the programmer to make sure he or she does not write past the end of arrays.

```

1  arr = new int[2];
2  arr[5] = 1;

```

This will compile, but will of course will give unpredictable results.

3.3 Expressions and Operators

3.3.1 Expressions

An expression is a collection of one or more operands and zero or more operators that can be evaluated to produce a value. A function that returns a value can be an operand as part of an expression. Additionally, parenthesis can be used to group smaller expressions together as part of a larger expression. A semicolon terminates an expression. Some examples of expressions include:

```

1 35 - 6;
2 foo(42) * 10;
3 8 - (9 / (2 + 1) );

```

The grammar for expressions is:

```

expr:
    INT_LITERAL
  |  STRING_LITERAL
  |  CHAR_LITERAL
  |  DOUBLE_LITERAL
  |  TRUE
  |  FALSE
  |  ID
  |  LPAREN expr RPAREN
  |  expr PLUS expr
  |  expr MINUS expr
  |  expr STAR expr
  |  expr DIVIDE expr
  |  expr EQ expr
  |  expr EXPO expr
  |  expr MODULO expr
  |  expr NEQ expr
  |  expr LT expr
  |  expr LEQ expr
  |  expr GT expr
  |  expr GEQ expr
  |  expr AND expr
  |  expr OR expr
  |  NOT expr
  |  AMPERSAND expr
  |  expr ASSIGN expr
  |  expr DOT expr
  |  expr POINTER_ACCESS expr
  |  STAR expr
  |  expr LBRACKET INT_LITERAL RBRACKET
  |  NEW prim_typ LBRACKET INT_LITERAL RBRACKET
  |  NEW STRUCT ID
  |  FREE LPAREN expr RPAREN
  |  ID LPAREN actual_opts_list RPAREN
  |  NULL LPAREN any_typ_not_void RPAREN

```

3.3.2 Assignment Operators

Assignment can be used to assign the value of an expression on the right side to a named variable on the left hand side of the equals operator. The left hand side can either be a named variable that has already been declared or a literal value:

```

1 int x;
2 int y;
3 x = 5;
4 y = x;
5 float y;
6 y = 9.9;

```

```
expr ASSIGN expr
```

All assignments are pass by value. Our language supports pointers and so pass by reference can be mimicked using addresses (explained below).

3.3.3 Arithmetic Operators

- + can be used for addition
- - can be used for subtraction (on two operands) and negation (on one operand)
- * can be used for multiplication
- / can be used for division
- ^ can be used for exponents
- % can be used for modular division
- & can be used to get the address of an identifier

The grammar for the above operators, in order, is as follows:

```
| expr PLUS expr
| expr MINUS expr
| expr TIMES expr
| expr DIVIDE expr
| expr EQ expr
| expr EXPO expr
| expr MODULO expr
| AMPERSAND expr
```

3.3.4 Comparison Operators

- == can be used to evaluate equality
- != can be used to evaluate inequality
- < can be used to evaluate is the left less than the right
- <= can be used to evaluate is the left less than or equal to the right
- > can be used to evaluate is the left greater than the right
- >= can be used to evaluate is the left greater than or equal to the right

The grammar for the above operators, in order, is as follows:

```
expr EQ      expr
expr NEQ     expr
expr LT      expr
expr LEQ     expr
expr GT      expr
expr GEQ     expr
```

3.3.5 Logical Operators

- ! can be used to evaluate the negation of one expression
- && can be used to evaluate logical and
- || can be used to evaluate logical or

The grammar for the above operators, in order, is as follows:

```
NOT  expr
expr AND  expr
expr OR   expr
```

3.3.6 Operator Precedence

We adhere to standard operator precedence rules.

```
/*
    Precedence rules
*/
%nonassoc NOELSE
%nonassoc ELSE
%right ASSIGN
%left OR
%left AND
%left EQ NEQ
%left LT GT LEQ GEQ
%left PLUS MINUS
%left STAR DIVIDE MODULO
%right EXPO
%right NOT NEG AMPERSAND
%right RBRACKET
%left LBRACKET
%right DOT POINTER_ACCESS
```

3.3.7 Order of Evaluation

Order of evaluation is dependent on the operator. For example, assignment is right associative, while addition is left associative. Associativity is indicated in the table above.

3.4 Statements

Statements include: **if**, **while**, **for**, **return**, **assert**, as well all expressions, as explained in the following sections. That is, statements include all expressions, as well as snippets of code that are used solely for their side effects.

```
stmt:
    expr SEMI
  | LBRACE stmt_list RBRACE
  | RETURN SEMI
  | RETURN expr SEMI
  | IF LPAREN expr RPAREN stmt ELSE stmt
  | IF LPAREN expr RPAREN stmt %prec NOELSE
  | WHILE LPAREN expr RPAREN stmt
```

```
| FOR LPAREN expr_opt SEMI expr SEMI expr_opt RPAREN stmt  
| ASSERT LPAREN expr RPAREN SEMI
```

3.4.1 If Statement

The if, else if, else construct will work as expected in other languages. Else clauses match with the closest corresponding if clause. Thus, there is no ambiguity when it comes to which if-else clauses match.

```
1 if (x == 42) {  
2     print("Gotcha");  
3 }  
4 else if (x > 42) {  
5     print("Sorry, too big");  
6 }  
7 else {  
8     print("I'll allow it");  
9 }
```

The grammar that recognizes an if statement is as follows:

```
IF LPAREN expr RPAREN stmt ELSE stmt  
| IF LPAREN expr RPAREN stmt %prec NOELSE
```

3.4.2 While Statement

The while statement will evaluate in a loop as long as the specified condition in the while statement is true.

```
1 /* Below code prints "Hey there" 10 times */  
2 int x = 0;  
3 while (x < 10) {  
4     print("Hey there");  
5     x = x + 1;  
6 }
```

The grammar that recognizes a while statement is as follows:

```
WHILE LPAREN expr RPAREN stmt
```

3.4.3 For Statement

The for condition will also run in a loop so long as the condition specified in the for statement is true. The expectation for a for statement is as follows:

```
for ( <initial state>; <test condition>; <step forward> )
```

Examples are as follows:

```
1 /* This will run as long as i is less than 100  
2    i will be incremented on each iteration of the loop */  
3 for (i = 0; i < 100; i = i + 1) {  
4     /* do something */  
5 }
```

The grammar that recognizes a for statement is as follows:

```
FOR LPAREN expr_opt SEMI expr SEMI expr_opt RPAREN
```

Note, since all variables must be declared at the beginning of functions, you can't declare i inside the "initial state" part of the for loop.

3.4.4 Code Blocks

Blocks are code that is contained within a pair of brackets, { code }, that gets executed within a statement. For example, any code blocks that follow an if statement will get executed if the if condition is evaluated as true:

```
1 int x = 42;
2 if (x == 42) {
3     /* the following three lines are executed */
4     print("Hey");
5     x = x + 1;
6     print("Bye");
7 }
```

The grammar that recognizes a block of code is as follows:

```
LBRACE stmt RBRACE
```

Code blocks are used to define scope. Local variables are always given precedence over global variables.

3.4.5 Return Statement

The return statement is used to exit out of a function and return a value. The return value must be the same type that is specified by the function declaration. Return can be used as follows:

```
1 /* The function trivially returns the input int value */
2 func int someValue(int x) {
3     return x;
4 }
```

The grammar that recognizes a return statement is as follows:

```
RETURN SEMI
RETURN expr SEMI
```

Note that functions can be declared as returning void, and don't need to use the return statement at all subsequently. Also, there should not be any code after return statements as is usual convention.

3.4.6 Assert Statement

The assert statement is used only for test cases. Thus, using assert outside of a test case will throw an error. Asserts wrap all tests with a given test case as the following illustrates:

```
1 func int add(int x, int y)
2 {
3     return x + y;
4 } with test {
5     assert(add(a,0) == 10);
6     assert(add(5,1) == 6);
7 } using {
8     int a;
9     int b;
10    a = 10;
11    b = 5;
12 }
```

Asserts ultimately get compiled into if-else statements.

3.5 Functions

Functions allow you to group snippets of code together that can subsequently be called from other parts of your program. All functions are global. You don't declare functions before defining them. To use functions from other Jateste files, you need to include those files at the top of your program using “`#include_jtlib <filename.jt>`”. If the file is your current directory, use quotations instead of carets.

3.5.1 Function Definitions

Function definitions contain the instructions to be performed when that function is called. The first part of the syntax is similar to how you define them in C, except the keyword “`func`” is additionally required. For example,

```
1 func int add(int x, int y) /* definition */
2 {
3     return x + y;
4 }
```

```
fdecl:
      FUNC any_typ ID LPAREN formal_opts_list RPAREN LBRACE vdecl_list stmt_list RBRACE
```

A functions can accept any type of formal arguments, except for void. Thus, functions can accept pointers as arguments, enabling the programmer to mimic pass by reference functionality. Note, variables must be declared at the top of each function. For example, the following is not allowed:

```
1 func int do_something(int x, int y) /* definition */
2 {
3     int c;
4     c = x + y;
5     int a; /* This is illegal. a must be declared at the top of this function,
6           above c = x + y; */
7     return c;
}
```

The following is the correct implementation of the above example:

```
1 func int do_something(int x, int y) /* definition */
2 {
3     int c;
4     int a;
5     c = x + y;
6     return c;
7 }
```

3.5.2 Calling Functions

A function is called using the name of the function along with any parameters it requires. You *must* supply a function with the parameters it expects. For example, the following will not work:

```
1 func int main()
2 {
3     add(); /* this is wrong and will not compile because add expects two ints as
4           parameters */
5     return 0;
6 }
7 func int add(int x, int y) /* definition */
8 {
```

```

8 return x + y;
9 }

```

Here's the grammar for a functional call:

```
ID LPAREN actual_opts_list RPAREN { Call($1, $3)}
```

Note, calling functions is simply another expression. This means they are guaranteed to return a value (except for void functions) and so can be used as part of other expressions. Of course, a function's return type must be compatible with the context it's being used in. For example, a function that returns a char cannot be used as an actual parameter to a function that expects an int. Consider the following:

```

1 func int main()
2 {
3   int answer = subtract(add(10,10), 10); /* this is ok */
4   int answer2 = subtract(add_float(10.0,10.0), 10); /* this is NOT ok because
5     subtract expects its first parameter to be an int while add_float returns a
6     float */
7   return 0;
8 }
9
10 func int add_int(int x, int y) /* definition */
11 {
12   return x + y;
13 }
14
15 func float add_float(float x, float y)
16 {
17   return x + y;
18 }
19
20 func int subtract(int x, int y)
21 {
22   return x - y;
23 }

```

Structs can be defined with methods. The syntax for calling these functions is slightly different as the following illustrates:

```

1 func int main()
2 {
3
4   struct house *my_house;
5   int price;
6   int vol;
7
8   my_house = new struct house;
9
10  my_house->set_price(100);
11  my_house->set_height(88);
12  my_house->set_width(60);
13  my_house->set_length(348);
14
15  price = my_house->get_price();
16  vol = my_house->get_volumne();
17
18  print(price);
19  print(vol);
20  return 0;

```

```

21 }
22
23 struct house {
24     int price;
25     int height;
26     int width;
27     int length;
28
29     method void set_price(int x)
30     {
31         price = x;
32     }
33
34     method void set_height(int x)
35     {
36         height = x;
37     }
38
39     method void set_width(int x)
40     {
41         width = x;
42     }

```

Thus, a variable of type “struct t” must be used with either “- >” (if the variable is stored on the heap) or “.” (if the variable is stored on the stack) to call the method associated with “struct t”.

3.5.3 Function Parameters

Formal parameters can be any data type including pointers, except “void”. Furthermore, they need not be of the same type. For example, the following is syntactically fine:

```

1 func void speak(int age, string name)
2 {
3     print_string ("My name is" + name + " and I am " + age);
4 }

```

```

formal_opts_list:
    /* nothing */
    | formal_opt

formal_opt:
    any_typ_not_void ID
    | formal_opt COMMA any_typ_not_void ID

```

While functions may be defined with multiple formal parameters, that number must be fixed. That is, functions cannot accept a variable number of arguments. As mentioned above, our language is pass by value. However, there is explicit support for passing pointers and addresses using * and &.

```

1 int* int_pt;
2 int a = 10;
3 int_pt = &a;

```

3.5.4 Recursive Functions

Functions can be used recursively. Each recursive call results in the creation of a new stack frame and new set of local variables. It is up to the programmer to prevent infinite loops.

3.5.5 Main Function

Each Jateste program must have a main function that serves as the entry point for execution.

3.5.6 Function Test Cases

Functions can be appended with test cases directly in the source code. Most importantly, the test cases will be compiled into a separate (executable) file as previously explained. The keyword “with test” is used to define a test case as illustrated here:

```
1 func int add(int a, int b); /* declaration */
2
3 func int add(int x, int y) /* definition */
4 {
5     return x + y;
6 }
7 with test {
8     assert(add(1,2) == 3);
9     assert(add(-1, 1) == 0);
10    assert(add(a, 2) == 4);
11 } using {
12     int a;
13     a = 2;
14 }
```

```
FUNC any_typ ID LPAREN formal_opts_list RPAREN LBRACE vdecl_list stmt_list RBRACE testdecl
testdecl:
    WTEST LBRACE stmt_list RBRACE usingdecl
```

Test cases contain a sets of boolean expressions, wrapped in assert statements. Multiple boolean expressions can be defined, they just must be separated with semi-colons. As shown above, the programmer may define as many tests within a given test case as he or she wants. Snippets of code can also be used to set up a given test case’s environment via the “using” keyword. That is, “using” is used to define code that is executed right before the test case is run. Consider the following:

```
1 func void changeAge(struct person *temp_person, int age)
2 {
3     *temp_person.age = age;
4 }
5 with test {
6     assert(sam.age == 11);
7 }
8 using {
9     struct person sam;
10    sam.age = 10;
11    changeAge(&sam, 11);
12 }
```

“using” is used to create a struct and then call function changeAge; thus it is setting up the environment for it’s corresponding test case. Variables defined in the “using” section of code can safely be referenced in the corresponding test case as shown. Basically, the code in the “using” section is executed right before the boolean expressions are evaluated and tested.

The “using” section is required, but can be left empty if desired

```
1
2 func int add(int x, int y) /* definition */
```

```

3 {
4 return x + y;
5 }
6 with test { /* variables a, b defined below are NOT in this test case's scope*/
7     add(10,2) == 12;
8     add(-1, 1) == 0;
9 }
10 using {
11
12 }

```

Test cases are compiled into a separate program which can subsequently be run. The program will run all test cases and output appropriate information. Here's an example of what the test executable could output:

```

1 Tests:
2 addtest tests:
3 add(a,0) == 10 passed
4 add(a,b) == 15 passed

```

Of course, it's possible tests fail. Consider the following source code:

```

1 func int add(int x, int y)
2 {
3     return x;
4 } with test {
5     assert(add(a,1) == 11);
6     assert(add(a,b) == 15);
7 } using {
8     int a;
9     int b;
10    a = 10;
11    b = 5;
12 }

```

The add function implementation is clearly wrong (it returns x, instead of x + y). After compiling and running the test executable we get:

```

1 Tests:
2 addtest tests:
3 add(a,1) == 11 failed
4 add(a,b) == 15 failed

```

4 Project Plan

4.1 Team Roles

From the onset of the project, we assigned roles among the team as was recommended. Andy came up with the idea for the language, so it seemed natural that he would be the Language Guru. All of us had input on the design of the language but we always consulted with Andy to ensure continuity with his vision for the project. Jake helped form the team, had good organization skills, and was on top of things from the start, so it seemed like he would be a good fit as the team Manager. Jake worked throughout the term to make sure that team meetings took place and deadlines were met. Jared had extensive experience with group projects and version control software, so he fell nicely into the role of System Architect. Jared drew up a work flow, based on pull requests, for our group to adhere to in order to ensure things went smoothly. Jemma had significant prior experience with testing and agreed to take the lead as the Tester for the team. Jemma worked to ensure that tests were created alongside of feature implementation to ensure that code was fully tested. As the project progressed, roles became more fluid as work was required in varying areas and everyone pitched in where things needed to get done. However, final say in any given area always remained with the assigned team member for that role.

4.2 Planning and Development

As a team, we made a commitment to meet weekly with David to make sure we were on the right track and to help answer any question we had about how to move forward. On weeks that we did not meet with David, we were conscious to meet as a team to discuss our progress over that week. Each week we identified tasks that needed to get done and assigned work for the week. We also utilized team meeting time to do research when necessary, and implement some feature together to make sure everyone was on the same page. We communicated throughout the week on our progress when it affected the work of another team member. Additionally, for tasks that could be picked up and implemented by anyone when they had a chance, we used a system of creating "issues" on GitHub that described portions of work that needed to get done. We also made some "milestones" on GitHub to motivate each other to get large segments of work done.

4.3 Testing Procedure

Throughout the writing of our compiler, we wrote tests to verify the functionality we were implementing. This served the twofold purpose of ensuring that we were generating the proper code output when we implemented new functionality, and also that we didn't break previously functioning parts of our compiler. Tests were written as canned recipes in a separate Makefile specifically written for our *tests* folder. These recipes compiled example programs from (.jt) source and checked the output of executing the compiled .ll code against a precomputed output that we paired with each source file. For compilation errors, we had a separate canned recipe to verify that the JaTeste compiler failed to finish compiling the bad source files.

4.3.1 Continuous Integration

As our testing suite became more complex, we decided to implement a continuous-integration build using Travis-CI that ensure that all pull requests to our master branch passed all existing tests before they could be merged. This helped reduce the need for a reviewer to actually download and compile all updates to make sure that no tests broke, which in turn increased the productivity of our team. In addition, all pushes to our master branch are built and tested in order to ensure that our master branch is always working.

Implementing continuous integration came with it's own challenges, as Travis-CI uses a containerized work flow to provide virtual testing environments with very little boot time. In order to run our build, we needed to find a way to install various dependencies, including OCaml and LLVM which were rather tricky to install on a Linux 12.04 Docker container. Once we were able to install all dependencies however, the continuous-integration system made testing our code a much simpler procedure.

Figure 1: Example commit list showing continuous integration build status next to commit SHA

Figure 2: Merging on Github with automatic continuous integration checks

4.4 Programming Style Guide

4.4.1 Comments

Comments used are to be associated with the code directly below the comment. Multi-line comments are allowed when necessary but discouraged. Keep comments concise and to one line when possible.

4.4.2 Naming Conventions

When possible, use names that are meaningful and relate to the use of the code. Function names are to be all lower case with underscores to separate words as `as_such`. Types are to be started with a capital and the rest of the deceleration will be lower case, with underscores to separate words As `As_such`. Variable names are to be all lower case with underscores separating words the same way functions are.

4.4.3 Indentation

Indent using tabs and set tabbing to 4 spaces for consistency. A new block of code should start on a new, indented line. A very long line can be broken into two lines, and the second line should be indented.

4.4.4 Parenthesis

Use parenthesis for chunks of code when necessary but avoid unnecessary parenthesis that clutters up the code.

4.5 Project Timeline

Date	Goal
1/29/16	Set group meeting, TA meeting, Come up with idea
2/5/16	Finish language proposal
2/12/16	Hash out specs of language, start LRM
2/19/16	Build scanner for the language
2/26/16	Build parser, finish LRM
3/4/16	Start working on AST
3/11/16	Spring Break
3/18/16	Continue work on AST, discuss code gen plan
3/25/16	Get up to speed on LLVM, work on AST
4/1/16	Finish AST, start SAST, code gen for "Hello, World"
4/8/16	Work on SAST, code gen, incremental testing
4/15/16	Implement code gen to two files, one for testing
4/22/16	Continue code gen / testing, automatic continuous integration
4/29/16	Finish automatic continuous integration, clean up code
5/6/16	Work on final report and presentation

4.6 GitHub Progression

Feb 7, 2016 – May 4, 2016

Contributions to master, excluding merge commits

Contributions: **Commits** ▼

As you can see from our chart, we were slow to start as we had to hash out the details of our language and did not involve a ton of code. The first major bump is at the time of the LRM deadline as a lot of code was written leading up to that deadline to get everything up and running. From that point on, we worked at a slow and steady pace, through the “Hello, World” deadline, and leading into the final deadline.

4.7 Software Development Environment

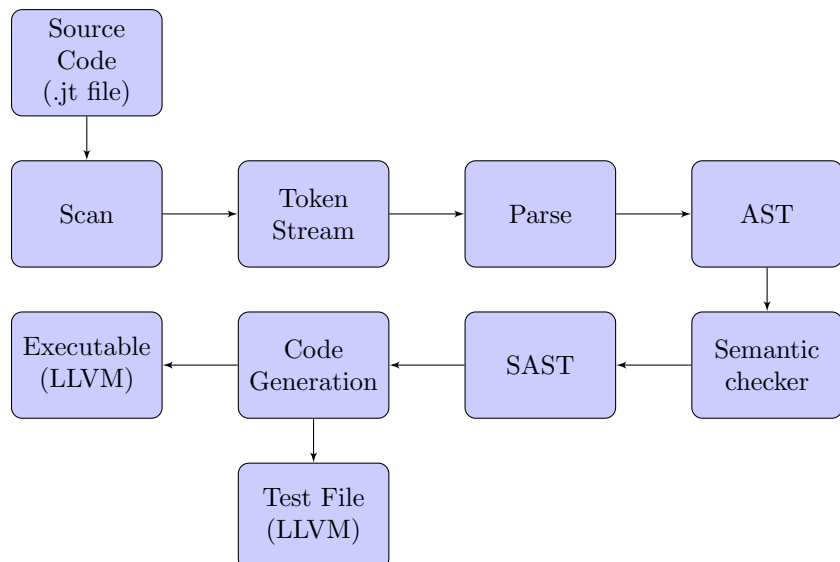

We used Git and a private GitHub repository for version control. Each team-member had their own private fork of the main repository for doing their own development. This allowed us to maintain a central master branch that was always working and passing tests. In order to merge into the master branch, we devised a work flow early based on reviewing pull requests from feature branches on each team-member’s fork. Each pull request was reviewed by another team-member, and later on in our development, we even added continuous integration to our build using Travis-CI to ensure that all tests were passing. We have since open-sourced this repository under the MIT license and it is available at <https://github.com/jaredweiss/JaTeste>

All of our compiler was written in OCaml, compiling .jt source code to LLVM. This was made easy by the fact that we were provided a VirtualBox image with OCaml and LLVM pre-installed (installing these dependencies on our Travis-CI builds was actually a fairly difficult task). For our CI builds, we installed OCaml (and ocamlfind via opam), make, and LLVM 3.8 as dependencies.

All submissions and reports were written in \LaTeX .

5 Architecture Design

5.1 Block Diagram

5.2 The Compiler

The entry point of the compiler for a given source.jt file is jatestest.ml. This is where the various phases of the compilation process are coordinated. At a high level, the compiler reads characters from source.jt, builds up an AST in the parser, performs a walk of the AST to create the SAST, passes the SAST on to codegen.ml, which finally generates the LLVM code.

As described in the introduction section the compiler is capable of producing two executables:

1. regular executable: source.ll
2. test executable: source-test.ll

Both can be run using the LLVM interpreter “lli”.

jatestest.ml is also where include files are handled. More specifically, if a given source file wants to include an external .jt file, jatestest.ml is where the given file is searched for.

5.3 The Scanner

The scanner reads characters from source.jt according to the regular expressions in scanner.ml and outputs a stream of tokens to parser.mly. The regular expressions for each token are in scanner.ml.

5.4 The Parser

The parser receives tokens from the scanner and creates an AST from the given context free grammar. The CFG is defined in parser.mly. At a high level, the AST is made up of a 4-element record:

```
1 type program = header list * bind list * func_decl list * struct_decl list
```

As illustrated, the AST consists of a list of header files, a list of global variables, a list of function definitions, and a list of struct definitions. If the parser is not able to build up an AST, it will throw a parsing error.

5.5 The Semantic Checker

The semantic checker receives the AST from the parser, walks the tree, and creates an SAST. The SAST carries additional information that helps the codegen phase of the compiler. For example, each array access is represented by a node in the AST; the SAST adds the array type information to such a node, which the AST does not.

An important part of the semantic checker is converting test cases into functions. More specifically, after checking the test case for a given function is semantically valid, `semant.ml` turns the test cases into standalone functions, where the `using` clause is copied and pasted to the top of the new function. Codegen is subsequently responsible for turning the new test case functions into standalone snippets of code.

If the semantic checker finds an error, it will immediately abort and print a relevant error message to the console.

5.6 The Code Generator

`codegen.ml` takes an SAST as input and creates LLVM code. We take advantage of OCaml's built in support for LLVM to help build the assembly code.

One of the most important jobs of the Code Generator is to create the test file. If instructed to, `codegen.ml` creates code for the test functions that were constructed as nodes in the SAST in the semantic checking phase. Importantly, `codegen.ml` ignores the user-defined main function, and calls the test functions from a brand new main. For example, consider the following snippet of code:

```
1 func int main()
2 {
3     Do_insightful_stuff;
4     return 0;
5 }
6
7
8 func int add(int x, int y)
9 {
10     return x + y;
11 } with test {
12     assert(add(a,0) == 10);
13 } using {
14     int a;
15     a = 10;
16 }
```

`codegen.ml` would compile this into the following pseudo-code test file:

```
1 func int main()
2 {
3     printResultOf: addtest();
4     return 0;
5 }
6
7
8 func int add(int x, int y)
9 {
10     return x + y;
11 }
12
13 func void addtest()
14 {
15     int a;
16     a = 10;
17     assert(add(a,0) == 10);
18 }
```

```
18 }
```

For the regular file, codegen.ml would compile the snippet of code into something like the following pseudo code:

```
1 func int main()
2 {
3     Do_insightful_stuff;
4     return 0;
5 }
6
7
8 func int add(int x, int y)
9 {
10     return x + y;
11 }
```

5.7 Supplementary Code

There is a Jateste standard library located in the lib folder. To include other jateste files in a given source code file, source.jt, the programmer has two options. If the file to include is in the current directory, the following syntax is used to include a file called file.jt:

```
1 #include_jtlib "file.jt"
```

If the file to include is in the standard library, use:

```
1 #include_jtlib <file.jt>
```

6 Test Plan

6.1 Test Suite Log

We wrote tests for every feature in the compiler. There are several small tests that we used to test individual elements such as structs, function calls, loops, etc. We included tests that were expected to pass, as well as tests that were expected to fail

Test Suite Log:

```
===== Running All Tests! =====
make[1]: Entering directory '/home/plt/JaTeste/test'
Makefile:23: warning: overriding recipe for target 'all-tests'
Makefile:15: warning: ignoring old recipe for target 'all-tests'
Testing 'hello-world.jt'
--> Test passed!
Testing 'global-scope.jt'
--> Test passed!
Testing 'test-func1.jt'
--> Test passed!
Testing 'test-func2.jt'
--> Test passed!
===== Runtime Tests Passed! =====
Testing 'local-var-fail.jt', should fail to compile...
--> Test passed!
Testing 'no-main-fail.jt', should fail to compile...
--> Test passed!
Testing 'return-fail1.jt', should fail to compile...
--> Test passed!
Testing 'struct-access-fail1.jt', should fail to compile...
--> Test passed!
Testing 'invalid-assignment-fail1.jt', should fail to compile...
--> Test passed!
Testing 'class1-var-fail1.jt', should fail to compile...
--> Test passed!
===== Compilation Tests Passed! =====

Testing 'test-class3.jt'  
—-> Test passed!  
===== All Tests Passed! =====
```

6.2 Test Automation

We had 34 tests in our test suite. In order to run all of the tests and see if they pass, run **make all** or **make test** in the src directory. This diffs the outputs of the tests with the files that we created that include expected outputs. If there are differences, it marks the test as a failure, otherwise it prints "Test passed!" as can be seen in the Test Suit Log

6.3 Tests

add-fail1.jt

```
1 func int main()  
2 {  
3   int a;  
4   string s;  
5  
6   a = 10;  
7   s = "cool";  
8  
9   a = a + s;  
10  
11  return 0;  
12 }
```

add-fail1.out

```
1 Scanned  
2 Parsed  
3 Fatal error: exception Exceptions.InvalidExpr("Illegal binary op")
```

class-fail1.jt

```
1 func int main()
2 {
3
4     struct house *my_house;
5     int price;
6     int vol;
7
8     my_house = new struct house;
9
10    my_house->set_price(100);
11    my_house->set_height(88);
12    my_house->set_width(60);
13    my_house->set_length(348);
14
15    price = my_house->get_price();
16    vol = my_house->get_volumne(10);
17
18    print(price);
19    print(vol);
20    return 0;
21 }
22
23 func void update_price(struct house *h, int a)
24 {
25     h->set_price(a);
26 } with test {
27     assert(my_house->price == 100);
28 } using {
29     struct house *my_house;
30     my_house = new struct house;
31     update_price(my_house, 100);
32 }
33
34 struct house {
35     int price;
36     int height;
37     int width;
38     int length;
39

7 Lessons Learned

7.1 Andrew Grant

One of the main things I learned was the importance of providing clean and well defined interfaces between the different parts of a large software systems project. There were a few times where we tried to work around the interfaces we had in place, but that only ended up costing us time. For example, at first our SAST was almost exactly the same as our AST. During code generation we often needed access to the types of certain variables. We created code in `codegen.ml` to do this for us, but it made a lot more sense to add that information to the SAST *while* performing semantic checking. Eventually we added this functionality, but having a clearer understanding of the interface between semantic checking and code generation would have served us well.

One thing I think we did well was start early. There wasn't really a time during the semester that we felt rushed, which I think ended up letting us think clearer and more rationally about how to tackle the next problem. For example, we were able to implement our testing functionality about three weeks before the project was due; this enabled us to focus on the presentation of the testing output, as well as add some simple object-oriented features to our language.

I also think we did a good job communicating with each other and working as a team. We were pretty much all present at most meetings. We met with David just about every week too which was very helpful. There was very little conflict which enabled us to focus on writing the compiler as opposed to wasting time arguing about unimportant things.

Overall I'm very proud of the project we were able to pull off given none of us have any compiler experience before.

7.2 Jemma Losh

I learned the importance of communication when tackling a large-scale group project. It can be difficult to make sure everyone is on the same page and up-to-date with the information they need to complete their portion. Weekly meetings helped our team with this aspect, but between these each group member had to be proactive in reaching out to others and coordinating ideas. The weekly meetings also allowed our team to work on the major key components together, so that everyone was able to understand the course of the project, and not just the parts they put work into. Overall, I was very lucky to have worked with a talented and well rounded team that had little problem with collaboration. For future teams I would suggest defining roles at the beginning, but realize that roles will become more fluid throughout the project, so be able to be flexible and put in work where it's needed.

7.3 Jared Weiss

I think this project helped us learn about working well as a team of software developers. Since we couldn't always work in the same room together, it was important to communicate well and make sure that 2 team members weren't working on the same thing. We needed to manually resolve a few merge conflicts when we started working on this project, but as we developed our git workflow and began using issues to track the work we were doing, there became a lot fewer conflicts. Furthermore, when we all worked together as a group in a library, I feel like we were able to get more work done more quickly since we were able to just ask our teammates simple questions and not need to wait for a response on a github issue tracker.

More regular 'hackathon'-style meetings would have likely made this project even easier, but overall I think we did a very good job of working together. Our roles were fairly well-defined and it was easy to know what each of us was supposed to be working on.

The one area we definitely could have done a little better was in our system of reviewing pull requests. At the start of this project, it was easy to get multiple sets of eyes on a pull request before merging, but as we progressed and the scope of each PR became more complicated, we stopped being as diligent with our reviews. This is why we ultimately ended up moving to a continuous-integration build system: to make sure that if a PR was merged, it didn't break any of the existing functionality. While having this extra layer of security in place is ultimately helpful, it still can't beat having teammates doing code review on every line.

7.4 Jake Weissman

This was a very rewarding experience for me as I got to work on a meaningful project with a team of people that I got along really well with. I'm happy to say that our team worked really well together and got along with little to no conflict. Beyond the joy of completing a really cool project, it was an added bonus to become such good friends with my teammates. As tough as the project was at times, we had some good laughs along the way and made the most out of it. My main takeaway from the project is that teamwork should be a project in itself. We are all smart and motivated students, but working together to such a great extent was a new experience for most of us and it took us some time to get into a groove of working together. There were some early struggles when we couldn't agree on our language, or decide on what we were going to compile down to, but we got through them and made decisions as a team with minimal personality clashes. I think it helped that we were all pretty easy going for the most part. As the project continued, we divided up work nicely and all tried to do our part, with time were people had to pick up the slack for others being inevitable. One comment I would make is that it might have been better to have more structure and more deadlines for our work - setting our own deadlines were often not enough motivation and things might have gotten done more smoothly and continuously if there were more regular, intermediate, deadlines to meet. Thankfully our group was motivated enough to get work done and we didn't have a ton to do at the last minute. All in all the project was a blast and I'm glad I had the opportunity to work with my awesome team!

8 Source Code

This section contains the JaTesté compiler source code. It includes the following files:

- `jateste.ml`
- `scanner.ml`
- `parser.mly`
- `ast.ml`
- `semant.ml`
- `sast.ml`
- `codegen.ml`
- `exceptions.ml`

All of the code is open source and available at <https://github.com/jaredweiss/JaTeste>
